# 1 Fully connected networks

In the previous notebook, you implemented a simple two-layer neural network class. However, this class is not modular. If you wanted to change the number of layers, you would need to write a new loss and gradient function. If you wanted to optimize the network with different optimizers, you'd need to write new training functions. If you wanted to incorporate regularizations, you'd have to modify the loss and gradient function.

Instead of having to modify functions each time, for the rest of the class, we'll work in a more modular framework where we define forward and backward layers that calculate losses and gradients respectively. Since the forward and backward layers share intermediate values that are useful for calculating both the loss and the gradient, we'll also have these function return "caches" which store useful intermediate values.

The goal is that through this modular design, we can build different sized neural networks for various applications.

In this HW #3, we'll define the basic architecture, and in HW #4, we'll build on this framework to implement different optimizers and regularizations (like BatchNorm and Dropout).

CS231n has built a solid API for building these modular frameworks and training them, and we will use their very well implemented framework as opposed to "reinventing the wheel." This includes using their Solver, various utility functions, and their layer structure. This also includes nndl.fc\_net, nndl.layers, and nndl.layer\_utils. As in prior assignments, we thank Serena Yeung & Justin Johnson for permission to use code written for the CS 231n class (cs231n.stanford.edu).

#### 1.1 Modular layers

This notebook will build modular layers in the following manner. First, there will be a forward pass for a given layer with inputs (x) and return the output of that layer (out) as well as cached variables (cache) that will be used to calculate the gradient in the backward pass.

```
def layer_forward(x, w):
```

```
""" Receive inputs x and weights w """
# Do some computations ...
z = # ... some intermediate value
# Do some more computations ...
out = # the output

cache = (x, w, z, out) # Values we need to compute gradients
```

```
return out, cache
```

The backward pass will receive upstream derivatives and the cache object, and will return gradients with respect to the inputs and weights, like this:

```
def layer_backward(dout, cache):
    """
    Receive derivative of loss with respect to outputs and cache,
    and compute derivative with respect to inputs.
    """
    # Unpack cache values
    x, w, z, out = cache

# Use values in cache to compute derivatives
    dx = # Derivative of loss with respect to x
    dw = # Derivative of loss with respect to w
return dx, dw
```

```
[2]: ## Import and setups
     import time
     import numpy as np
     import matplotlib.pyplot as plt
     from nndl.fc_net import *
     from cs231n.data_utils import get_CIFAR10_data
     from cs231n.gradient_check import eval_numerical_gradient,_
     →eval_numerical_gradient_array
     from cs231n.solver import Solver
     import os
     #alias kk os._exit(0) #piazza question @247 said it was okay for this to be_
      \rightarrow commented out
     %matplotlib inline

     %autoreload 2
     def rel_error(x, y):
       """ returns relative error """
```

```
return np.max(np.abs(x - y) / (np.maximum(1e-8, np.abs(x) + np.abs(y))))
```

```
[4]: # Load the (preprocessed) CIFAR10 data.

data = get_CIFAR10_data()
for k in data.keys():
    print('{}: {} '.format(k, data[k].shape))

X_train: (49000, 3, 32, 32)
y_train: (49000,)
X_val: (1000, 3, 32, 32)
y_val: (1000,)
X_test: (1000, 3, 32, 32)
```

#### 1.2 Linear layers

y\_test: (1000,)

In this section, we'll implement the forward and backward pass for the linear layers.

The linear layer forward pass is the function affine\_forward in nndl/layers.py and the backward pass is affine\_backward.

After you have implemented these, test your implementation by running the cell below.

#### 1.2.1 Affine layer forward pass

Implement affine\_forward and then test your code by running the following cell.

```
[8]: # Test the affine_forward function
     num_inputs = 2
     input\_shape = (4, 5, 6)
     output dim = 3
     input_size = num_inputs * np.prod(input_shape)
     weight_size = output_dim * np.prod(input_shape)
     x = np.linspace(-0.1, 0.5, num=input_size).reshape(num_inputs, *input_shape)
     w = np.linspace(-0.2, 0.3, num=weight_size).reshape(np.prod(input_shape),_
     →output_dim)
     b = np.linspace(-0.3, 0.1, num=output_dim)
     out, _ = affine_forward(x, w, b)
     correct_out = np.array([[ 1.49834967, 1.70660132, 1.91485297],
                             [ 3.25553199, 3.5141327, 3.77273342]])
     # Compare your output with ours. The error should be around 1e-9.
     print('Testing affine_forward function:')
     print('difference: {}'.format(rel_error(out, correct_out)))
```

```
Testing affine_forward function: difference: 9.769847728806635e-10
```

#### 1.2.2 Affine layer backward pass

Implement affine backward and then test your code by running the following cell.

```
[10]: # Test the affine backward function
      x = np.random.randn(10, 2, 3)
      w = np.random.randn(6, 5)
      b = np.random.randn(5)
      dout = np.random.randn(10, 5)
      dx_num = eval_numerical_gradient_array(lambda x: affine_forward(x, w, b)[0], x,_
       →dout)
      dw num = eval numerical gradient array(lambda w: affine forward(x, w, b)[0], w, u
       →dout)
      db num = eval numerical gradient array(lambda b: affine forward(x, w, b)[0], b, u
      →dout)
      _, cache = affine_forward(x, w, b)
      dx, dw, db = affine_backward(dout, cache)
      # The error should be around 1e-10
      print('Testing affine_backward function:')
      print('dx error: {}'.format(rel_error(dx_num, dx)))
      print('dw error: {}'.format(rel_error(dw_num, dw)))
      print('db error: {}'.format(rel_error(db_num, db)))
```

Testing affine\_backward function: dx error: 8.919089805724145e-11 dw error: 3.3166638698134875e-10 db error: 5.337512722200738e-12

# 1.3 Activation layers

In this section you'll implement the ReLU activation.

# 1.3.1 ReLU forward pass

Implement the relu\_forward function in nndl/layers.py and then test your code by running the following cell.

```
[11]: # Test the relu_forward function

x = np.linspace(-0.5, 0.5, num=12).reshape(3, 4)

out, _ = relu_forward(x)
```

Testing relu\_forward function: difference: 4.999999798022158e-08

# 1.3.2 ReLU backward pass

Implement the relu\_backward function in nndl/layers.py and then test your code by running the following cell.

```
[12]: x = np.random.randn(10, 10)
dout = np.random.randn(*x.shape)

dx_num = eval_numerical_gradient_array(lambda x: relu_forward(x)[0], x, dout)

_, cache = relu_forward(x)
dx = relu_backward(dout, cache)

# The error should be around 1e-12
print('Testing relu_backward function:')
print('dx error: {}'.format(rel_error(dx_num, dx)))
```

Testing relu\_backward function: dx error: 3.2756291991801495e-12

# 1.4 Combining the affine and ReLU layers

Often times, an affine layer will be followed by a ReLU layer. So let's make one that puts them together. Layers that are combined are stored in nndl/layer\_utils.py.

#### 1.4.1 Affine-ReLU layers

We've implemented affine\_relu\_forward() and affine\_relu\_backward in nndl/layer\_utils.py. Take a look at them to make sure you understand what's going on. Then run the following cell to ensure its implemented correctly.

```
[13]: from nndl.layer_utils import affine_relu_forward, affine_relu_backward

x = np.random.randn(2, 3, 4)

w = np.random.randn(12, 10)

b = np.random.randn(10)

dout = np.random.randn(2, 10)
```

```
out, cache = affine_relu_forward(x, w, b)
dx, dw, db = affine_relu_backward(dout, cache)

dx_num = eval_numerical_gradient_array(lambda x: affine_relu_forward(x, w, u \to b)[0], x, dout)
dw_num = eval_numerical_gradient_array(lambda w: affine_relu_forward(x, w, u \to b)[0], w, dout)
db_num = eval_numerical_gradient_array(lambda b: affine_relu_forward(x, w, u \to b)[0], b, dout)

print('Testing affine_relu_forward and affine_relu_backward:')
print('dx error: {}'.format(rel_error(dx_num, dx)))
print('dw error: {}'.format(rel_error(dw_num, dw)))
print('db error: {}'.format(rel_error(db_num, db)))
```

Testing affine\_relu\_forward and affine\_relu\_backward:

dx error: 1.8537958763052795e-10 dw error: 4.850293045582865e-10 db error: 1.7509270163983791e-09

#### 1.5 Softmax and SVM losses

You've already implemented these, so we have written these in layers.py. The following code will ensure they are working correctly.

```
[14]: num classes, num inputs = 10, 50
      x = 0.001 * np.random.randn(num_inputs, num_classes)
      y = np.random.randint(num_classes, size=num_inputs)
      dx num = eval numerical gradient(lambda x: svm loss(x, y)[0], x, verbose=False)
      loss, dx = svm_loss(x, y)
      # Test sum loss function. Loss should be around 9 and dx error should be 1e-9
      print('Testing svm_loss:')
      print('loss: {}'.format(loss))
      print('dx error: {}'.format(rel_error(dx_num, dx)))
      dx_num = eval_numerical_gradient(lambda x: softmax_loss(x, y)[0], x,_u
       →verbose=False)
      loss, dx = softmax_loss(x, y)
      # Test softmax_loss function. Loss should be 2.3 and dx error should be 1e-8
      print('\nTesting softmax loss:')
      print('loss: {}'.format(loss))
      print('dx error: {}'.format(rel error(dx num, dx)))
```

Testing svm\_loss:

loss: 9.000376553518647

dx error: 3.038735505103329e-09

Testing softmax\_loss: loss: 2.302623185303025

dx error: 8.274214690524093e-09

# 1.6 Implementation of a two-layer NN

In nndl/fc\_net.py, implement the class TwoLayerNet which uses the layers you made here. When you have finished, the following cell will test your implementation.

```
[16]: N, D, H, C = 3, 5, 50, 7
      X = np.random.randn(N, D)
      y = np.random.randint(C, size=N)
      std = 1e-2
      model = TwoLayerNet(input_dim=D, hidden_dims=H, num_classes=C, weight_scale=std)
      print('Testing initialization ... ')
      W1_std = abs(model.params['W1'].std() - std)
      b1 = model.params['b1']
      W2_std = abs(model.params['W2'].std() - std)
      b2 = model.params['b2']
      assert W1_std < std / 10, 'First layer weights do not seem right'
      assert np.all(b1 == 0), 'First layer biases do not seem right'
      assert W2 std < std / 10, 'Second layer weights do not seem right'
      assert np.all(b2 == 0), 'Second layer biases do not seem right'
      print('Testing test-time forward pass ... ')
      model.params['W1'] = np.linspace(-0.7, 0.3, num=D*H).reshape(D, H)
      model.params['b1'] = np.linspace(-0.1, 0.9, num=H)
      model.params['W2'] = np.linspace(-0.3, 0.4, num=H*C).reshape(H, C)
      model.params['b2'] = np.linspace(-0.9, 0.1, num=C)
      X = np.linspace(-5.5, 4.5, num=N*D).reshape(D, N).T
      scores = model.loss(X)
      correct_scores = np.asarray(
        [[11.53165108, 12.2917344, 13.05181771, 13.81190102, 14.57198434, 15.
       \rightarrow 33206765, 16.09215096],
         [12.05769098, 12.74614105, 13.43459113, 14.1230412, 14.81149128, 15.
       →49994135, 16.18839143],
         [12.58373087, 13.20054771, 13.81736455, 14.43418138, 15.05099822, 15.
       \rightarrow66781506, 16.2846319]])
      scores_diff = np.abs(scores - correct_scores).sum()
      assert scores_diff < 1e-6, 'Problem with test-time forward pass'
      print('Testing training loss (no regularization)')
      y = np.asarray([0, 5, 1])
      loss, grads = model.loss(X, y)
```

#### 1.7 Solver

We will now use the cs231n Solver class to train these networks. Familiarize yourself with the API in cs231n/solver.py. After you have done so, declare an instance of a TwoLayerNet with 200 units and then train it with the Solver. Choose parameters so that your validation accuracy is at least 40%.

```
since you did it in the previous notebook.
# ----- #
#pick some random hyperparameters and hope it works LOL
model = TwoLayerNet(hidden_dims=200, reg=0.3)
solver = Solver(model, data, update rule = 'sgd',
              optim_config = {'learning_rate': 8.5 * 1e-4,},
              num_epochs=10, batch_size=215
              , lr_decay=0.95,
              print_every=100)
solver.train()

class TwoLayerNet(object):
  A two-layer fully-connected neural network with ReLU nonlinearity and
  softmax loss that uses a modular layer design. We assume an input dimension
  of D, a hidden dimension of H, and perform classification over C classes.
  The architecure should be affine - relu - affine - softmax.
 Note that this class does not implement gradient descent; instead, it
  will interact with a separate Solver object that is responsible for running
  optimization.
  The learnable parameters of the model are stored in the dictionary
  self.params that maps parameter names to numpy arrays.
  HHHH
 def __init__(self, input_dim=3*32*32, hidden_dims=100, num_classes=10,
              dropout=0, weight_scale=1e-3, reg=0.0):
   Initialize a new network.
   Inputs:
   - input dim: An integer giving the size of the input
    - hidden_dims: An integer giving the size of the hidden layer
   - num_classes: An integer giving the number of classes to classify
    - dropout: Scalar between 0 and 1 giving dropout strength.
    - weight_scale: Scalar giving the standard deviation for random
     initialization of the weights.
    - req: Scalar giving L2 regularization strength.
   self.params = {}
   self.reg = reg
    # =========== #
    # YOUR CODE HERE:
      Initialize W1, W2, b1, and b2. Store these as self.params['W1'],
      self.params['W2'], self.params['b1'] and self.params['b2']. The
      biases are initialized to zero and the weights are initialized
    # so that each parameter has mean 0 and standard deviation weight_scale.
      The dimensions of W1 should be (input_dim, hidden_dim) and the
      dimensions of W2 should be (hidden_dims, num_classes)

   return loss, grads
class FullyConnectedNet(object):
```

```
11 11 11
A fully-connected neural network with an arbitrary number of hidden layers,
ReLU nonlinearities, and a softmax loss function. This will also implement
dropout and batch normalization as options. For a network with L layers,
the architecture will be
\{affine - [batch norm] - relu - [dropout]\} x (L - 1) - affine - softmax
where batch normalization and dropout are optional, and the {...} block is
repeated L - 1 times.
Similar to the TwoLayerNet above, learnable parameters are stored in the
self.params dictionary and will be learned using the Solver class.
def __init__(self, hidden_dims, input_dim=3*32*32, num_classes=10,
            dropout=0, use_batchnorm=False, reg=0.0,
            weight_scale=1e-2, dtype=np.float32, seed=None):
  11 11 11
 Initialize a new FullyConnectedNet.
 Inputs:
  - hidden_dims: A list of integers giving the size of each hidden layer.
  - input_dim: An integer giving the size of the input.
  - num_classes: An integer giving the number of classes to classify.
  - dropout: Scalar between 0 and 1 giving dropout strength. If dropout=0 then
    the network should not use dropout at all.
  - use batchnorm: Whether or not the network should use batch normalization.
  - reg: Scalar giving L2 regularization strength.
  - weight_scale: Scalar giving the standard deviation for random
    initialization of the weights.
  - dtype: A numpy datatype object; all computations will be performed using
    this datatype. float32 is faster but less accurate, so you should use
   float64 for numeric gradient checking.
  - seed: If not None, then pass this random seed to the dropout layers. This
    will make the dropout layers deteriminstic so we can gradient check the
   model.

Computes the forward pass for an affine (fully-connected) layer.

cs231n.stanford.edu.

def affine\_forward(x, w, b):

n n n

```
The input x has shape (N, d_1, \ldots, d_k) and contains a minibatch of N
 examples, where each example x[i] has shape (d_1, \ldots, d_k). We will
 reshape each input into a vector of dimension D = d_1 * ... * d_k, and
 then transform it to an output vector of dimension M.
 Inputs:
 - x: A numpy array containing input data, of shape (N, d_1, ..., d_k)
 - w: A numpy array of weights, of shape (D, M)
 - b: A numpy array of biases, of shape (M,)
 Returns a tuple of:
 - out: output, of shape (N, M)
 - cache: (x, w, b)
 # ------ #
 # YOUR CODE HERE:
 # Calculate the output of the forward pass. Notice the dimensions
   of w are D x M, which is the transpose of what we did in earlier
 # assignments.
 # ----- #
 #hint from Piazza
 out = np.dot(x.reshape(x.shape[0], -1), w) + b
 # ------ #
 # END YOUR CODE HERE
 cache = (x, w, b)
 return out, cache
